Summary

## Theorem

*Non-entangling  $R$ -matrices cannot form topological invariants*

- Entanglement: acting on a particle at one place will influence it very, very far away.
- Non-entangling: a physical process (operator) that cannot form entangled states from non-entangled states
- Knot Invariants: A unique property of a knot.
- This entire investigation is motivated by a pun!

Summary

- Each knot has a unique Jones polynomial.
- The Jones polynomial has many connections to quantum physics.
- The Jones polynomial is related to the Kauffman bracket polynomial - the knot invariant we used in this study.

$$\text{Crossing} = A \cdot \text{Resolution 1} + A^{-1} \cdot \text{Resolution 2}$$

Figure: The Bracket Relation

# Reidemeister Moves and Topology

- Satisfying these moves will preserve topological properties

Figure: The Reidemeister moves

# The Bracket Polynomial

- The bracket satisfies Reidemeister moves II and III.
- It does NOT satisfy Reidemeister I.
- We can introduce a corrective factor to account for Reidemeister I.

$$\begin{aligned} X(\text{crossing}) &= (-A^3)^{-w(\text{crossing})} \cdot \langle \text{crossing} \rangle \\ &= (-A^3)^{-(w(\text{cup})-1)} \cdot (-A^{-3} \langle \text{cup} \rangle) \\ &= (-A^3)^{-w(\text{cup})} \cdot \langle \text{cup} \rangle \\ &= X(\text{cup}) \end{aligned}$$

Theorem

Summary

- The general form of the bracket is given by

$$\langle K \rangle = \sum_S \langle K|S \rangle d^{|S|-1}$$

, where  $d = (-A^2 - A^{-2})$ .

- The normalization of the oriented bracket is given by

$$f_k = (-A^3)^{-w(K)} \langle K \rangle \in \mathbb{Z}[A, A^{-1}]$$

, where  $w(K)$  is the writhe (sum of oriented crossings).

Q.L.I's

Theorem and  
Proof  
Theorem

Summary

- Entanglement is the correlation of quantum states.
- Mathematically, we say that a quantum process  $G$  is entangling if there is a vector

$$|\alpha\beta\rangle = |\alpha\rangle \otimes |\beta\rangle \in V \otimes V$$

such that  $G|\alpha\beta\rangle$  cannot be written as a tensor product.

### Remark

We have methods to measure how entangling an operator is.

# Quantum Link Invariants

- Knots can be represented by particles moving through space with respect to time.
- These particles are created in pairs (cups) and annihilate subsequently in pairs (caps).

Figure: A knot formed from vacuum-vacuum processes

- Diagrammatically, we can break up a knot into pieces.
- Each piece can be given a "quantum" matrix representation.

$$R = \textit{Overcrossing} \quad (1)$$

$$\bar{R} = \textit{Undercrossing} \quad (2)$$

$$M = \textit{Cup or Cap} \quad (3)$$

Theorem

Summary

Figure: Quantum link invariants in action!

- Cups/caps  $M$  and crossings  $R$  in knots can be given matrix representations.

$$R = \begin{pmatrix} (A^{-1}) & 0 & 0 & 0 \\ 0 & (-A^2 + A^{-1}) & A & 0 \\ 0 & A & 0 & 0 \\ 0 & 0 & 0 & (A^{-1}) \end{pmatrix}$$

$$M = \begin{pmatrix} 0 & (iA) \\ (-iA^{-1}) & 0 \end{pmatrix}$$

Theorem

Summary

- From an  $R$  matrix like the one shown, topological invariants can be produced.
- All the examples we can calculate show that entanglement is a necessary condition.

## Conjecture

Can topology and entanglement be linked through this process?

Theorem

Summary

- Quantum link invariants need entanglement in order to be topological invariants.
- Topology, Knot Theory, and Quantum Theory are intimately related.
- We still do not understand the extent of the relationship between entanglement and topology.
- Outlook
  - We may be able to employ some techniques from gauge theory and algebraic topology to better understand entanglement strength.
